Appendix C

PAVEMENT CONDITION REPORT

Data Calculation - The surface of the pavement is typically tested using the Laser Road Surface Tester (RST). This device consists of various sensors and lasers specialized for collecting data related to surface distress. This data is augmented by subjective analysis. Data on cracking, rutting, roughness (ride quality) and external factors are calculated during the surface condition survey. This data is then processed to produce various condition numbers, which are shown in the Pavement Condition Report.

The Pavement Condition Report gives detailed information about each individual section of pavement. This listing is also in numerical order by section number, and includes the street name and limits. The numerical fields, and their relative values, are described in more detail below.

RUT CONDITION An average rut depth for the section is calculated in real time by the RST. A percentage of distance where the rut exceeded 10 mm and 20 mm is also recorded which allows analysis of localized ruts. These figures are combined using an algorithm, which yields a RUT condition number between 10 and 100 where 100 is the best.

ROUGHNESS CONDITION In order to calculate the Ride Quality Number, 3 devices are used. The lasers in the wheel path continuously measure the distance from the vehicle to the pavement. An accelerometer is integrated to determine the continuous vertical position of the vehicle. A distance measuring device is used to record the position and velocity of the vehicle. These figures are used to calculate the longitudinal profile of the pavement in the time domain. A theoretical roughness model is then superimposed on the profile to determine the quality of the ride, as perceived by passengers. The "RQ" rating varies from 10 to 100, where 100 is best.

CRACK CONDITION The CRACK rating figure, varying from 10 to 100 where 100 is best, is based on the size, number, and types of cracks objectively counted and measured by the laser test vehicle or manual collection. The crack number also includes the influence of other surface defects such as raveling and bleeding.

EXTERNAL CONDITION There are parameters collected during the surface collection that deal with conditions off the pavement that affect pavement deterioration these include climate zone, pavement edge profile, shoulder or curb condition and drainage condition. These parameters combine to form and external condition number.

SURFACE CONDITION Rut, Roughness and Crack conditions are weighted and combined to form the Surface Condition number.

PAVEMENT CONDITION The surface condition along with any structural condition information provided are weighted and combined then external conditions are deducted to form the Pavement Condition Number. This number, like all other condition numbers, ranges from 10 to 100 where 100 is best.

RUT DEPTH The rut depth is listed in terms of average depth for the block section in inches.

IRI The International Roughness Index is listed for each block section indicating the inches of vertical roughness per mile traveled down the pavement.

Note: The data has not been aged and therefore reflects the condition **IN THE YEAR IT WAS TESTED.**
